Introduction

The Computer Forensics Tool Testing (CFTT) project is the joint effort of the National Institute of Justice, the National Institute of Standards and Technology (NIST), the U. S. Department of Defense, the Technical Support Working Group, and other related agencies. The objective of the CFTT project is to provide measurable assurance to practitioners, researchers, and other applicable users that the tools used in computer forensic investigations provide accurate results. Accomplishing this requires the development of specifications and test methods for computer forensic tools and subsequent testing of specific tools against those specifications.

The test results provide the information necessary for developers to improve tools, users to make informed choices, and the legal community and others to understand the tools’ capabilities. The use of well-recognized methodologies for conformance and quality testing serves as the foundation of our approach for testing computer forensic tools. Plus, in an effort to further develop the specifications and test methods, we encourage the entire forensics community to visit the CFTT Web site (http://www.cftt.nist.gov), where drafts are accessible for both commentary and review.

This document reports the results from testing one commonly used disk imaging tool, dd as provided with FreeBSD 4.4, against Disk Imaging Tool Specification, Version 3.1.6, developed by the CFTT staff and available at http://www.cftt.nist.gov/DI-spec-3-1-6.doc. This specification identifies the top-level disk imaging tool requirements as—

- The tool shall make a bit-stream duplicate or an image of an original disk or partition.
- The tool shall not alter the original disk.
- The tool shall log I/O errors.
- The tool’s documentation shall be correct.

Note: The test methodology is for software tools that copy or image hard disk drives. It does not cover analog media or digital media such as cell phones or personal digital assistants (PDAs).

Test results from other software packages and the CFTT test methodology can be found on NIJ’s Computer Forensic Tool Testing Web page, http://www.ojp.usdoj.gov/nij/sciencetech/cftt.htm.
Test Results for Disk Imaging Tools:  
dd Provided with FreeBSD 4.4

Tool Tested: dd execution environment utility provided with FreeBSD 4.4

Operating System: FreeBSD 4.4-RELEASE #0 released 9/01

Supplier: FreeBSD Foundation
Address: 7321 Brockway Drive
         Boulder, CO 80303
Web: http://www.freebsd.org

1. Results Summary by Requirements

The tool shall make a bit-stream duplicate or an image of an original disk or partition.
For all 32 test cases that were run, the dd utility produced an accurate bit-stream duplicate or an
image on disks or partitions of all disk sectors copied.

The tool shall not alter the original disk.
For all the test cases that were run, a SHA-1 hash was created on the source. Another SHA-1
hash was created on the source after the test case was run. In all cases, the hash codes matched
(i.e., the source was not altered).

The tool shall be able to verify the integrity of a disk image file.
This requirement does not apply to dd.

The tool shall log I/O errors.
Assertions requiring read or write errors were not tested. The dd utility did produce a log
message that there was no space left on the destination when the source was greater than the
destination.

The tool documentation shall be correct.
No errors were found in the documentation supplied.

2. Anomalies

No anomalies were observed.

3. Test Case Selection

The test cases were selected from the Linux test cases of Disk Imaging Tool Specification,
Version 3.1.6. Although these test cases were developed for disk imaging tools running in the
Linux environment, these cases are suitable for any UNIX-like environment such as FreeBSD.
Not all of the 52 test cases specified in *Disk Imaging Tool Specification, Version 3.1.6* apply to FreeBSD dd.

The primary criterion for selecting a test case is the existence of a tool feature that is covered by the objective of the test case as defined by the test case summary from *Disk Imaging Tool Specification, Version 3.1.6*. For example, test case DI(Linux)-1 calls for the following setup: *Copy a LINUX IDE source disk to a LINUX IDE destination disk where the source disk is smaller than the destination.* Since every parameter specified in the setup can be applied to dd, test case DI(Linux)-1 is used. However, for test case DI-17, detecting a corrupted image file, the test case is not used since dd does not detect whether an image file has been changed. In practice, this would be accomplished with a separate program such as md5sum.

### 3.1 Inapplicable Test Cases

Test cases that met the following criteria were designated as not applying to dd testing:

- Test cases that use a corrupted image file do not apply since this is not supported by dd.
- Test cases that require removable magnetic media such as tape were not run.

### 3.2 Selected Test Cases

The following 32 test cases were used to test dd in the FreeBSD environment. Each line of the table describes one test case. The **Case** column identifies the test case. The **Op** column indicates the type of operation, either to create a copy of the source or to create and image file. The **Src** column indicates the type of interface used to connect the source drive to the test PC. The **Dst** column indicates the type of interface used to connect the destination drive to the test PC. The **Rel Size** column indicates the relative size of the source drive to the destination drive. All test cases with the **Obj** parameter value of *Disk* are operations on the entire physical hard drive. All test cases with the **Obj** parameter value equal to a partition type (e.g., FAT16, etc.) are operations on a logical drive (a partition). The entries in the **Err** column indicate the type of error introduced for the test. However, this parameter was not used for the dd test cases.

4. Test Results by Assertion

This section presents the results of dd testing with results grouped by assertion. The assertions are taken from *Disk Imaging Tool Specification, Version 3.1.6.*

### 4.1 Mandatory Assertions

**AM-1.** If a source is accessed by the tool, then the source will not be altered.

After each source disk is created, a SHA-1 hash value is calculated and saved. Each time the tool is run, another SHA-1 hash is calculated after the run and compared to the saved value. For all test cases that were run, the hash codes matched (i.e., the source was not altered).

The column labeled **Case** is the test case ID. **Before SHA-1** is the first four and last four digits (in hexadecimal) of the SHA computed on the source disk before running any test cases. **After SHA-1** is the first four and last four digits (in hexadecimal) of the SHA computed on the source disk after executing dd for the given test case. The **SHA Values Match?** column indicates if the full hash values match.

AM-2. If there are no errors reading from a source or writing to a destination, then a bit-stream duplicate of the source will be created on the destination.

The column labeled **Case** is the test case ID. The type of object copied (disk or partition) is indicated in the **Obj** column. The column labeled **Src** is the number of sectors on the source to be copied. The column labeled **Dst** is the number of sectors on the destination. The numbers of sectors compared are listed in the **Compared** column. The column **Not Matched** indicates the number of sectors that were expected to compare equal but were different.

AM-3. If there are errors reading from a source or writing to a destination, then a qualified bit-stream duplicate of the source will be created on the destination. The identified areas are replaced by values specified by the tool’s documentation.

This assertion was not tested.

AM-4. If there are errors reading from the source or writing to the destination, then the error types and locations are logged.

This assertion was not tested.

AM-5. If the source or destination is an IDE or SCSI drive and an image or bit-stream duplicate is created, then the interface used is presumed to be well defined.\(^1\)

See all test cases.

AM-6. If the expected result of any test defined in this specification is achieved and the documentation was followed without change in achieving this result, then the documentation is presumed correct.

No errors were observed in the documentation of dd obtained from the manual (man) entry.

AM-7. If a bit-stream duplicate of a source is created on a larger destination, then the contents of areas on the destination that are not part of the duplicate are set to values as specified in the tool documentation.

The column labeled **Case** is the test case ID. The type of object copied is indicated in the **Obj** column. The **Do BF** column indicates that dd should never backfill. The **Excess** column indicates the number of excess sectors on the destination. The number of excess sectors backfilled with a user-specified value is indicated in the **BF** column. The number of excess destination sectors that were not changed by dd is indicated in the **Not BF** column. The values in the **BF** and **Not BF** columns do not apply for cases 10, 23, and 38 because NTFS and Linux partitions, unlike FAT partitions, have formatting information in the excess sectors. Consequently, the values in the **BF** and **Not BF** columns for these three test cases should be ignored. Cases 10, 23, and 38 require extra steps to verify that the excess sectors are not changed by the dd command.

\(^1\) The actual assertion from the specification refers to a specific requirement from the spec. The essence of the referenced requirement is for the interface to be well defined.
When a FAT partition is formatted, the sectors in the lower addresses are modified to contain the FAT table and other information. The sectors in the high addresses are not changed and retain any content from before the partition is formatted. Therefore, the content of the excess sectors can be reliably known. However, NTFS and Linux ext2 partitions have control information (e.g., inodes) scattered throughout the partition. Therefore, to verify that the excess sectors are undisturbed by dd, a hash of the excess sectors is computed before and after running dd. The before hash for each case appears in Table 4-1. The after hash appears in Table 4-2. If the excess sectors are unchanged, then the hash values are the same.

### 4.2 Optional Assertions

**AO-1.** If a hash of one or more blocks (i.e., less than the entire disk) from the source is computed before duplication and is compared to a hash of the same blocks from the destination, the hashes will compare equal.

This assertion was not tested.

**AO-2.** If more than one partition exists on the source disk, the tool will produce a duplicate of any user-selected source partition on the destination.

See the results for the following test cases. Each line of the table describes one test case. The **Case** column identifies the test case. The **Op** column indicates the type of operation, either to create a copy of the source or to create and image file. The **Src** column indicates the type of interface used to connect the source drive to the test PC. The **Dst** column indicates the type of interface used to connect the destination drive to the test PC. The **Rel Size** column indicates the relative size of the source drive to the destination drive. All test cases with the **Obj** parameter value of **Disk** are operations on the entire physical hard drive. All test cases with the **Obj** parameter value equal to a partition type (e.g., FAT16, etc.) are operations on a logical drive (a partition). The entries in the **Err** column indicate the type of error introduced for the test. However, this parameter was not used for the dd test cases.

**AO-3.** If a partition exists on the source, the tool will display or log a message indicating that the partition exists and display or log one or more items of information from the following list: drive indicator, device type, device address or mount point, size, space used, and free space.

This product does not provide the functionality described.
AO-4. If the tool logs the tool version, it will be the version referred to in the implementation’s documentation.

This product does not provide the functionality described.

AO-5. If the subject disk identification is available and the tool is capable of logging the subject disk identification, then the subject disk identification will be logged.

This product does not provide the functionality described.

AO-6. If the tool logs the source partition table in human readable form and the information from the source partition table can be ascertained independently from the tool, then the source partition table information will accurately match the content of the independent partition table information.

This product does not provide the functionality described.

AO-7. If the tool logs errors and any error occurs, then the type and location of the error will be logged.

This assertion was not tested.

AO-8. If the tool logs tool actions and the tool’s documentation states what actions are logged, then the actions logged will accurately match those documented in the tool’s documentation.

This product does not provide the functionality described.

AO-9. If the tool logs start and finish run times, then the logged start and finish run times will accurately match those recorded by the tester according to screen input images, test input scripts, or tester notes.

This product does not provide the functionality described.

AO-10. If the tool logs tool settings and the tool’s documentation states what settings are logged, then the logged settings will accurately match those set by the tester or as documented in the tool’s documentation.

This product does not provide the functionality described.

AO-11. If the tool logs user comments, then the logged user comments will accurately match those entered by the tester as captured in screen input images, test input scripts, or tester notes.

This product does not provide the functionality described.
AO-12. If the tool creates image files, then it will create an image file of a source on a magnetic medium that can be removed from the platform on which it was created.

Suitable magnetic tape removable media were not available. Small (less than 250MB) media, such as floppy disks or zip disks, were not considered useful for imaging hard drives and therefore, were not tested.

AO-13. If the tool creates an image file from a source on a removable magnetic medium, then a duplicate of the source created from the removable magnetic medium will result in a duplicate on the destination, and the destination will compare equal to the source.

Suitable magnetic tape removable media were not available. Small (less than 250MB) media, such as floppy disks or zip disks, were not considered useful for imaging hard drives and therefore, were not tested.

AO-14. If an image file is created, and there are no errors reading from a source, nor errors writing to a destination, then a bit-stream duplicate created from the image file will compare equal to the source.

The results for image files are included in the results for the mandatory assertions. The following test cases are for image files. Each line of the table describes one test case. The **Case** column identifies the test case. The **Op** column indicates the type of operation, either to create a copy of the source or to create and image file. The **Src** column indicates the type of interface used to connect the source drive to the test PC. The **Dst** column indicates the type of interface used to connect the destination drive to the test PC. The **Rel Size** column indicates the relative size of the source drive to the destination drive. All test cases with the **Obj** parameter value of *Disk* are operations on the entire physical hard drive. All test cases with the **Obj** parameter value equal to a partition type (e.g., FAT16, etc.) are operations on a logical drive (a partition). The entries in the **Err** column indicate the type of error introduced for the test. However, this parameter was not used for the dd test cases.

5. Testing Environment

The tests were run in the NIST CFTT lab. This section describes the hardware (test computers and hard drives) available for testing. Not all components were used in testing. The following host computers were available for execution of test cases: Paladin, HecRamsey, McCloud, McMillan, AndWife, Cadfael, Rumpole, Wimsey, and JudgeDee. More than 25 hard drives (13 different models and 6 different brands) were used for the tests (Table 5-1). The tests were run with hard drives arranged in one of several possible configurations (Table 5-4), as required by the test parameters.

5.1 Extended BIOS Host Computers

Cadfael, Rumpole, Wimsey, and JudgeDee have the following hardware components in common:

Table 5-1. Extended BIOS Host Computer Hardware Components

</tr>
</tbody>
</table>

Rumpole also had a 30GB OnStream SC30 tape drive (not used in the test procedures). JudgeDee had a third slot for a removable IDE hard disk drive.

Paladin, HecRamsey, McCloud, McMillan, and AndWife have the following hardware components in common:

5.2 Hard Disk Drives

The hard disk drives that were used were selected from the drives listed in Table 5-3. These hard drives were mounted in removable storage modules. Any combination of two IDE hard drives and two SCSI hard drives can be installed in Paladin, HecRamsey, McCloud, McMillan, AndWife, Cadfael, Rumpole, Wimsey, or JudgeDee as required for a test. The legacy BIOS computers can have only two IDE drives mounted at a time.

The IDE disks used in the legacy BIOS computers have jumpers set manually to drive 0 for source drives and drive 1 for destination drives, and the media drive is set to either 0 or 1 depending on the drive slot available after either the source or destination drive is installed. The IDE disks used in Paladin, HecRamsey, McCloud, McMillan, AndWife, Cadfael, Rumpole, Wimsey, and JudgeDee have jumpers set for cable select.

The SCSI ID for the SCSI disk is set to either 0 or 1 as required by the test case. Except as noted, a source disk is set to ID 0, and a destination disk is set to ID 1.

5.3 Test Configurations

The host computer and hard drive setup were determined by the test case parameters. Two or three disk drives were required for each test case. Source, destination, and media disks were required for all test cases. The source disk provides something to copy. The destination disk provides a place to put the copy. The media disk provides a place to put the image file for test cases that require the creation of an image file. The media disk also provides the runtime FreeBSD environment for running `dd`. A DOS Boot floppy was used to create the runtime environment for the test case; it contained control scripts and log files. A CD–ROM contained the support and utility software. The support software provided for setup of test data, measurement of test results, and control of the test process.

For all the `dd` tests, one of the following extended BIOS computers were selected: Paladin, HecRamsey, McCloud, McMillan, AndWife, Cadfael, Rumpole, Wimsey, or JudgeDee. None of the Nexar computers were used.

The source disk interface and type of source partition determined the source disk selection. A disk was selected with the matching interface that contained a partition of the type required for the test case. The destination interface and the relative size parameters determined the selection of the destination drive. A drive was selected with the specified interface and, for whole-disk operations, size relative to the source. For partition operations, the actual size of the destination drive did not matter because the size of the partition on the destination was relevant. After the source and destination drives were selected, the media disk was selected for one of the two available drive slots.

The 12 system hard drive configurations used for the tests are presented in Table 5-4. The Step column indicates the phase of the test to which the configuration applies. The Source column indicates where the source drive was mounted. The drive was usually positioned as primary drive 1. SCSI source drives were set to SCSI ID 0. The Destination column indicates the positioning of the destination drive. The Media column indicates the positioning of the media drive.

5.4 Support Software

FS-TST Release 1.0 was developed to support the testing of disk imaging tools. FS-TST Release 1.0 can be obtained from http://www.cftt.nist.gov. The support software serves five main functions: initialization of a disk to a known value (DISKWIPE), comparison of a source with a destination (DISK CMP, PART CMP, ADJ CMP, and SECCMP), detection of changes to a disk (DISK HASH and SECHASH), corruption of an image file (CORRUPT), and simulation of a faulty disk [BADDISK and BADX13]. All programs (except for BADDISK and BADX13) were written in ANSI C and compiled with the Borland C++ compiler version 4.5. BADDISK and BADX13 were written in assembler language and compiled with Borland Turbo Assembler version 5.0.

5.5 Basic Structure of Test Cases

A test case has five parts: setup, execution of the tool to acquire an image, execution of the tool to add the image to the case file, execution of the tool to restore the image to a destination drive, and measurement of the results. The setup for the test case was done in the DOS environment and involved the following steps:

1. Initialize a source disk to a known value.
2. Hash the source disk and save the hash value.
3. Initialize a destination disk to a known value.
4. If the test requires a partition on the destination, then create and format a partition on the destination disk. If the test uses a destination partition larger than the source partition and the partition type is either NTFS or Linux, then compute a reference hash of the excess sectors of the destination partition.
5. If the test uses an image file, partition and format a media disk and load FreeBSD to the media disk.

Note that steps 1, 2, and 5 are performed once and then used for several test cases.

The tool execution was done in the FreeBSD environment. The steps in this execution phase were:

1. If an image file is required, use the tool to create an image file of the source on the media disk.
2. Use the tool to create the destination disk by either restoring an image file of the source to the destination or copying the source to the destination.

Measurement of the test results had four steps:

1. Compute a hash of the source disk and compare the computed hash value to the saved hash value. If the hashes are the same, then the tool has not altered the source disk.
2. Compare the source to the destination to determine what sectors match and the disposition of any excess destination sectors.
3. Examine the tool log file for any expected messages. For example, if the destination is too small, then there should be a message indicating the condition.
4. If the test uses a destination partition larger than the source partition and the partition type is either NTFS or Linux, then compute a hash of the excess sectors of the destination partition. If this hash agrees with the reference hash of the excess sectors, then the excess sectors are unchanged by dd.

6. Test Results Summary Key

A summary of the actual test results is presented in this report. The following table presents a description of each section of the test results summary.

<table>
<thead>
<tr>
<th>Heading</th>

</tbody>
</table>

7. Interpretation of Test Results

There are six main questions of interest when examining the results of a test case:

- Is the source disk unchanged?
- Have the correct number of sectors been accurately copied?
- Has the tool alerted the user to a destination smaller than the source?
- Has the tool handled excess destination sectors correctly as specified?
- Has the tool detected changes to an image file?
- Has the tool alerted the user to any I/O errors?
7.1 Source Disk

The integrity of the source disk is checked by comparing the hash of the source disk computed before any tests are run with the hash computed after the tool is used. If the two hash values differ, then the tool has changed the source disk. The reference hash is recorded in the Source disk setup box, and the hash computed after the tool is run is recorded in the Log file highlights box.

7.2 Number of Sectors Copied

The number of sectors that should be copied is the minimum of the number of source sectors and the number of destination sectors. This value can be found on the sectors compared line of the Log file highlights box. If the next line of the Log file highlights box, sectors differ, is not zero, then the tool did not correctly copy all the sectors that should have been copied. The logical block addresses of the first few sectors not copied correctly are listed on the diffs range line.

The number of sectors in the source and destination can be determined as follows: If the tool operated on an entire disk, then the size of the source and destination can be found in the Disks box. If the tool operated on a single partition, then the partition sizes are presented in the partition tables in the Log file highlights box. The partitions used in the test are identified in the /select option parameters to the PARTCMP program execution presented in the Execute box. The /select option is followed by two parameters: the partition numbers of the source and destination partitions.

7.3 Small Destination Detection

The tool should issue a message indicating that the destination is smaller than the source for any test case defined for a smaller destination. The message is captured from the stderr file produced by dd and is reproduced in the Log file highlights box.

7.4 Excess Sectors

For disk operations, the tool should leave the contents of excess sectors as is. The tool action can be verified by the entries labeled Zero fill, Other fill, and Dst byte fill, giving the count of sectors in each category. The number of excess sectors is indicated in the Log file highlights box by the line with the text “… Source (…) has [number of excess sectors] fewer sectors ….”

For test cases 10, 23, and 38, additional steps are required to verify that the tool has not altered any excess sectors. When a FAT partition is formatted, the sectors in the lower addresses are modified to contain the FAT table and other information. The sectors in the high addresses are not changed and retain any content from before the partition is formatted. Therefore, the content of the excess sectors can be reliably known. However, NTFS and Linux ext2 partitions have control information (e.g., inodes) scattered throughout the partition. Therefore, to verify that the excess sectors are undisturbed by dd, a hash of the excess sectors is computed before and after
running dd. The before hash appears in the Log file highlights box and is labeled Before dd. The after hash appears in the Log file highlights box and is labeled After dd. If the excess sectors are unchanged, then the hash values are the same.

### Case DI(Linux)-02 for FreeBSD 4.4 dd

**Case Summary:** Copy a LINUX IDE source disk to a LINUX IDE destination disk where the source disk is the same size as the destination.

**Tester Name:** JRL  
**Test Date:** Mon Oct 21 08:23:30 2002  
**PC:** McCloud

**Disks:**
- **Source:** DOS Drive 80 Physical Label F5  
  - IBM-DTLA-307020 with 40188960 sectors
- **Destination:** DOS Drive 81 Physical Label F7  
  - IBM-DTLA-307020 with 40188960 sectors
- **Image media:** DOS Drive 80 Physical Label 93  
  - WD300BB-00CAA0 with 58633344 sectors

**Windows 98 [Version 4.10.2222] DOS boot floppy with run scripts CD-ROM with PartitionMagic Pro 6.0 and FS-TST Release 1.0**

**Source disk setup:**
- Dual boot Linux/Windows Me with EXT2 & Fat16
- Disk: F5
- Host: Cadfael
- Operator: JRL  
- OS: WindowsMe/Linux
- Date: Sat Aug 11 11:13:43 2001

**Source disk setup tools:**
- `DISKWIPE.EXE F5_SRC Cadfael 80 F5 /src`
- `X:\pm\pqmagic /cmd=X:\pm\fat-src.txt`
- `Load Operating System to Source disk`
- `DISKHASH.EXE F5_SRC Cadfael 80 /before`

**Destination:**
- `Z:\\ss\DISKWIPE.EXE 02 McCloud 81 F7 /noask /dst /new_log /comment JRL`

**Destination Setup:**
- Boot to DOS
  - `Z:\\ss\DISKWIPE.EXE 02 McCloud 81 F7 /noask /dst /new_log /comment JRL`
- Boot to FreeBSD
  - `Z:\\ss\dd_copy (copy)`

**Expected**
- **Source disk is unchanged**

---

**Completion Note:**
- The text represents a technical report on disk operations, including setup, execution, and measurement logs. It details the configuration and procedures used for transferring data between drives, ensuring no changes to the source disk. The report includes specific commands, log files, and expected outcomes. The technical details, such as partition types and sector counts, are meticulously documented to ensure clarity and accuracy in the documentation process.
Results: src compares equal to dst

Actual Results: No anomalies

Analysis: Expected results achieved

Case DI(Linux)-14 for FreeBSD 4.4 dd

Case Summary:
Copy a LINUX IDE source disk
to a LINUX SCSI destination disk
where the source disk is larger than the destination

Tester Name: SN
Test Date: Mon Oct 21 14:36:30 2002
PC: McCloud

Disks:
Source: DOS Drive 80 Physical Label A5
Destination: DOS Drive 81 Physical Label 13
Image media: DOS Drive 80 Physical Label 93
A5 is a WDC WD200BB-00AUA1 with 39102336 sectors
13 is a FUJITSU MAN3184MC with 35885447 sectors
93 is a WDC WD300BB-00CACA0 with 58633344 sectors
Windows 98 [Version 4.10.2222] DOS boot floppy with run scripts
CD-ROM with PartitionMagic Pro 6.0 and FS-TST Release 1.0

Source disk setup:
Fat32 only
Disk: A5
Host: JudgeDee
Operator: JRL
OS: NoOs
Options: none
Date: Mon Apr 15 14:35:04 2002

About the National Institute of Justice

NIJ is the research, development, and evaluation agency of the U.S. Department of Justice. The Institute provides objective, independent, evidence-based knowledge and tools to enhance the administration of justice and public safety. NIJ's principal authorities are derived from the Omnibus Crime Control and Safe Streets Act of 1968, as amended (see 42 U.S.C. §§ 3721–3723).

The NIJ Director is appointed by the President and confirmed by the Senate. The Director establishes the Institute’s objectives, guided by the priorities of the Office of Justice Programs, the U.S. Department of Justice, and the needs of the field. The Institute actively solicits the views of criminal justice and other professionals and researchers to inform its search for the knowledge and tools to guide policy and practice.

Strategic Goals
NIJ has seven strategic goals grouped into three categories:

Creating relevant knowledge and tools
1. Partner with State and local practitioners and policymakers to identify social science research and technology needs.
2. Create scientific, relevant, and reliable knowledge—with a particular emphasis on terrorism, violent crime, drugs and crime, cost-effectiveness, and community-based efforts—to enhance the administration of justice and public safety.
3. Develop affordable and effective tools and technologies to enhance the administration of justice and public safety.

Dissemination
4. Disseminate relevant knowledge and information to practitioners and policymakers in an understandable, timely, and concise manner.
5. Act as an honest broker to identify the information, tools, and technologies that respond to the needs of stakeholders.

Agency management
6. Practice fairness and openness in the research and development process.
7. Ensure professionalism, excellence, accountability, cost-effectiveness, and integrity in the management and conduct of NIJ activities and programs.

Program Areas
In addressing these strategic challenges, the Institute is involved in the following program areas: crime control and prevention, including policing; drugs and crime; justice systems and offender behavior, including corrections; violence and victimization; communications and information technologies; critical incident response; investigative and forensic sciences, including DNA; less-than-lethal technologies; officer protection; education and training technologies; testing and standards; technology assistance to law enforcement and corrections agencies; field testing of promising programs; and international crime control.

In addition to sponsoring research and development and technology assistance, NIJ evaluates programs, policies, and technologies. NIJ communicates its research and evaluation findings through conferences and print and electronic media.
